Introduction

DuPont pressboards come in three specific densities, offering a range of mechanical properties to meet a variety of applications. Low density Type 992 is available in two thicknesses. Medium density Type 993 is available in six thicknesses. Type 994 is a densified version of Type 993 and comes in fourteen thicknesses.

No special equipment is required to cut, mill, sand, drill, rout or punch NOMEX® brand pressboard. Standard equipment used with other insulating materials such as cellulose board or polyester/glass laminates works very well.

Since all pressboard is sensitive to moisture, prolonged exposure to a humid environment is not advised. Store pressboard in low relative humidity areas and/or wrap it in plastic or a similar air impermeable material.

In addition to facilitating efficient cutting and machining, the tools, methods, and recommendations outlined in this brochure also encourage high-yield operations with limited waste. Waste can add substantial cost to the finished product.

Be sure to follow all standard safety precautions when performing any of the various cutting or machining operations outlined in this brochure. Power equipment will generate dust. Use a dust collection system or wear a NIOSH-approved mask.

Cutting

Shears

Pressboard Types 992 and 993
Pressboards with thicknesses up to .160” (4.0 mm) may be cut with shears.

Pressboard Type 994
Pressboard with thicknesses up to ~0.080” (2.0 mm) can be cut with shears. Since Type 994 is more dense, thicker varieties are best cut with a circular saw, band saw, or reciprocating saw.

**Circular saw**

Use any fine-tooth, raker set blade that is appropriate for wood (e.g., 10” (250 mm) diameter, carbide tipped for longer life, 60 teeth or 7-1/4” (184 mm) diameter carbide blade with 24 teeth).

Note: Table comparison using 10” (250 mm) diameter blade
** Back the exit side of the material with masking tape. In addition, use masonite, LUCITE® or an equivalent material as an exit side bushing.

**Wire — diamond wire**

Wire cutting generates very little heat. Kerf loss is small and yield is high.

| Wire diameter: | 0.010” (.25 mm) |
| Wire speed:    | 200’/min. (6.1 m/min) |
| Cut gap:       | 0.012” (.30 mm) |
| Feed Rate:     | 0.50”/min. (12.7 mm/min) |

**High-speed Jewelers Saw Blade**

This is an effective, high-yield method for cutting pressboard. However, it is slow.

| Diameter:      | 2” (51 mm) |
| Cut gap:       | 0.030” (.76 mm) |
| Thickness:     | 0.032” (.81 mm) |
| Speed:         | 12,500 RPM (water lube) |
| Feed Rate:     | 3”/minute (76 mm/min) |

**Thurston Manufacturing**
(401) 331-0243 www.thurstonsaws.com
**Band Saw**

Some fuzz will occur on bottom of cut. However, fuzziing can be reduced by closing the tolerance on the support plate.

Backig the pressboard also reduces fuzziing. Use tempered masonite or equivalent as an exit side bushing. At the minimum, if this material is unavailable, back the pressboard with masking tape.

</tbody>
</table>

**Water Jet Cutter**

Causing no warpage, delamination or fuzziing on the edges, the water jet is an excellent way to cut pressboard. However, pressboard is sensitive to moisture and must be wiped dry soon after cutting. Be sure to store it on a flat surface in a dry area with low relative humidity.

Equipment is expensive, but there are businesses available that provide water jet cutting for hire.

Cut gap: 0.035" (0.89 mm) width cutting stream (Often depends on machine specs).

Nozzle orifice: 0.009" (0.23 mm) (Often depends on machine specs).

Pressure: 40,000-45,000 lbs/in² (27.6-31.0 kN/cm²)

Feed Rate: 24"/min. (610 mm/min) [With or without sand; with for a much better cut].

Rate depends on the thickness of the material and the finish requirements.

**Note:** Because all pressboard is sensitive to moisture, prolonged exposure to a humid environment is not advised. Store pressboard in low relative humidity areas and/or wrap it in plastic or a similar air impermeable material.

**Ultrasonic Cutting**

Because they cut pressboard in a slicing action, ultrasonic machines can leave a slightly raised edge which, depending on processing requirements, may require some light sanding. In addition, ultrasonics can cause some discoloration due to the “charring” of the pressboard. **Note:** There is no waste with this method.

Laser Cutter
Particles can distort the laser beam to cause inaccurate cutting. In addition, laser cutting causes “charring” (discoloration) along the edges of the NOMEX® brand pressboard. This cutting method is not recommended.

Cast Cutter
For specialty work, when speed is not a consideration, the cast cutter is a surprisingly safe and effective way to cut pressboard. High speed oscillation produces the cutting action. The blade cuts on both the forward and the backward stroke, and if it touches the operator, in most cases, it will do no harm.

Die Cutting
Die cutting is a quick, efficient method ideal for mass production work. There are all sorts of dies available to processors, including steel ruled dies, presharpened self-standing dies, heavyweight forged dies, and machined dies for complicated cuts. Matching the right die to the application is essential. Key considerations are the pressboard type and thickness and the edge quality requirements. A consultation with a professional die/punch manufacturer can be most beneficial.

In all cases, be sure to back the pressboard with a high quality cutting pad made of nylon, rubber composition, or polypropylene. Mount the pad to a 1” (25 mm) thick die board or marine plywood to ensure quality results. After extensive use, cutting pads can be resurfaced by sanding or milling. As a general rule, the cutting pad should be as hard as or harder than the material being die cut. Type 994 — die cutting is usually limited to thicknesses no greater than 0.125” (3.2 mm).

Note: Die cutting may leave a slightly raised edge.

Stryker Instruments (800) 253-3210 www.inst.strykercorp.com

Sanding
When working with a belt sander, use 120 to 320 grit aluminum oxide or silicon carbide sanding belts. It is always a good idea to experiment first with different sanding belts to determine which work best. A rotary sander will also work well.

Use standard equipment. No special equipment is required. Remember, power equipment will create dust. Use a dust collection system or wear a NIOSH-approved mask.

Milling

Pressboard Types T992 and T993
Use standard milling equipment, the same equipment used with cellulose board.

Pressboard Type T994
Because of its density, Type 994 can melt if cut too fast. It’s best to work at slower speeds to prevent the material from overheating. It’s advisable to first test feed and speed rates.

Punching

When punching NOMEX® brand pressboard, as with die cutting, key considerations include the type and thickness of the pressboard and the edge quality requirements. Unfortunately, misapplication of tooling is quite common as processors all too often opt for too much rather than what is appropriate to do the job. A consultation with a professional punch/die manufacturer can be most beneficial.

Pressboard options: Use a punch and die set with tight tolerances — 0.0002” - 0.0005” (5.1 - 12.7 µm) maximum on the diameter. Ideally, the punch should be made of tungsten carbide and used to size the tool steel die. In some situations, a male/female tool in a die set for use in a punch press is appropriate. In others, a simple hole punch and a quality cutting pad made of nylon, rubber composition, or polypropylene (to back the pressboard) will suffice. Once again, matching the right tool to the application is fundamentally important. Type 994 — Punching is usually limited to thicknesses no greater than 0.125” (3.2 mm). NOTE: Punching may leave a slightly raised edge.

Progressive Service Die Co. (717) 766-8004 www.psdcdies.com

Drilling

Use bits normally recommended for wood and masonite. The carbide tipped variety will have a much longer life span. A typical twist drill will work well at speeds above 1000 RPM. For best hole quality, use a brad point drill with two flutes at 3000 RPM.

Normally, this drill type is not required. With both drills types, a slow feed rate works best.

Snap-On-Tools (800) 926-5544 www.snapon.com

Routing

Use a split helix router bit (tungsten carbide for longer life) with either two or four helixes. Operating speed should be between 20,000 and 27,000 RPM.
